SLIMCHAIN: SCALING BLOCKCHAIN TRANSACTIONS THROUGH OFF-CHAIN STORAGE AND PARALLEL PROCESSING

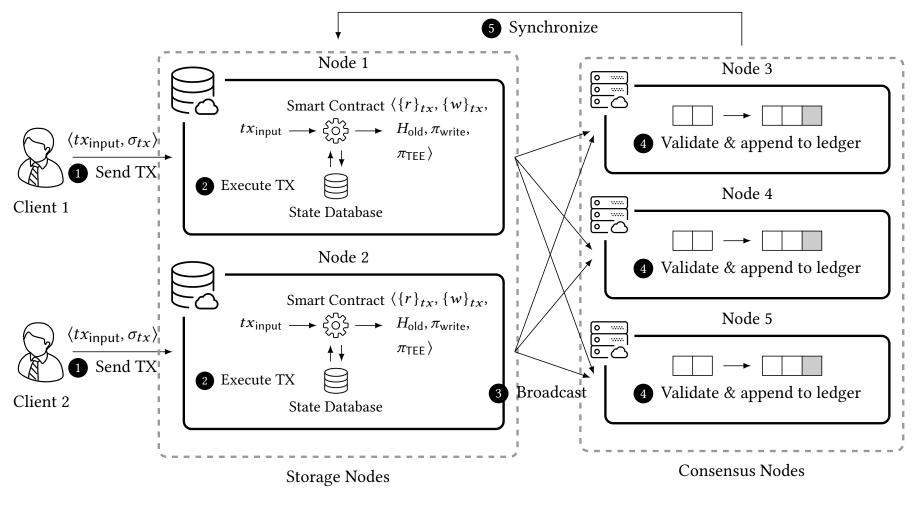

Cheng Xu^{1,2}, Ce Zhang², Jianliang Xu², and Jian Pei¹

¹Simon Fraser University, Canada ²Hong Kong Baptist University, Hong Kong {chengxu, cezhang, xujl}@comp.hkbu.edu.hk jpei@cs.sfu.ca

Motivation and System Model

• Issues of Current Blockchain System:

- -Every node keeps a full replication of transaction history and ledger states.
- -Every node needs to validate each transaction in block.
- -High storage (ETH full node: 870GB) and execution Transaction should be processed in parallel overhead.
- Challenges:
- Transaction contains arbitrary logic
 - \Rightarrow Novel proof techniques to ensure integrity of transaction execution
- Transaction introduces arbitrary sized read/write set \Rightarrow Extra design to support on-chain commitment updates

- Stateless design:
- -Move ledger states and transaction executions offchain to a subset of nodes.
- Reduce the on-chain load.

 \Rightarrow New method for validating and committing concurrent transactions

- Transaction Processing Workflow:
 - **1** Send TX **2** Verifiable TX execution **3** Broadcast
 - **4** Validate & append to ledger **5** Synchronize

Fig. 1: System Model

Off-chain Transaction Execution

• Inside TEE:

- -Generate the read/write set $\{r\}_{tx}, \{w\}_{tx}$ w.r.t. the current state H_{old} .
- -Get the read set Merkle proof π_{read} and verify it w.r.t. $\{r\}_{tx}$.
- -Compute the TEE proof π_{TEE} w.r.t. $\{r\}_{tx}, \{w\}_{tx}, H_{\text{old}}$.
- Outside TEE:
- -Get the write set Merkle proof π_{write} .
- **Broadcast** $tx_{submit} = \langle tx_{input}, \{r\}_{tx}, \{w\}_{tx}, H_{old}, \pi_{TEE}, \pi_{write} \rangle$:
- $-\pi_{\text{TEE}}$ ensures the execution integrity and the read integrity.
- $-\{r\}_{tx}, \{w\}_{tx}, H_{old}, \pi_{write}$ provide enough information for on-chain validation and commitment.

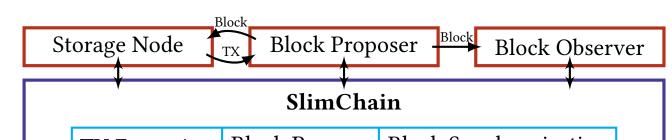

Node Synchronization

• Block Observer

- Validate and log blocks created by the block proposers.
- -Compress π_{write} to reduce network transmission.
- Storage Node
- Execute the similar procedure as on-chain transaction commitment.
- Keep transaction data and state data.
- Maintain full Merkle tree instead of partial tree \mathcal{T}_w .

Implementation

• Implement in Rust program language (LOC: 26,000).

On-chain Transaction Commitment

• Challenges:

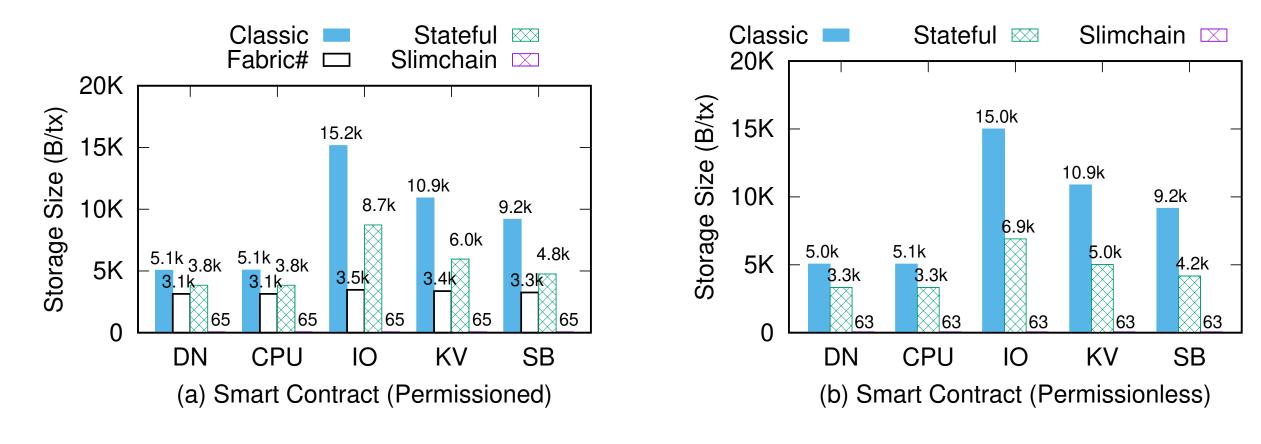

- -How to update the state commitment without access to the full tree?
- -How to check conflict among transactions and ensure serializability?
- Our Solution: Keep track of temp state of recent k blocks.
- $-\mathcal{T}_w$: a partial Merkle tree w.r.t. the write set in the past k blocks.
- $-M_{i\mapsto r}, M_{i\mapsto w}$: map between block height to read, write addresses.
- $-M_{r\mapsto i}, M_{w\mapsto i}$: map between read, write addresses to an ordered list of block heights.
- Procedure:
- Discard TX is older than recent k blocks.
- -Validate $\pi_{\text{TEE}}, \pi_{\text{write}}$.
- -Check conflict of $\{r\}_{tx}, \{w\}_{tx}$.
- OCC: Check whether other committed transactions have modified the data that the current transaction accessed.
- SSI: Check *write-write conflict* and whether there are *rw-dependencies* both pointing to and originating from the current transaction.
- Update ledger state commitment over \mathcal{T}_w and generate new block.
- Update \mathcal{T}_w : take the Merkle proof π_{write} and write set $\{w\}_{tx}$ to apply the writes from the transaction.
- \circ Tidy \mathcal{T}_w : remove the write addresses whose age is more than k blocks.

- Two consensus protocols are implemented: PoW, Raft.
- Source code is available at https://git.io/slimchain.

	TX Executi	ose	Block Synd	chronization	_					
	Off-chain State			On-chain State		-				
	Cons	TX Engine								
Ē	Low-level Modules									
	Storage	Merkle Trie		Network	SGX Enclave
